

Minimizing Electric Field Stress in Surge Arresters

Minimizing Electric Field Stress in Surge Arresters

The voltage distribution along the resistors in a surge arrester is uneven due to stray capacitances. It is possible to reduce the maximum electric field stress by a careful choice of position for the grading rings.

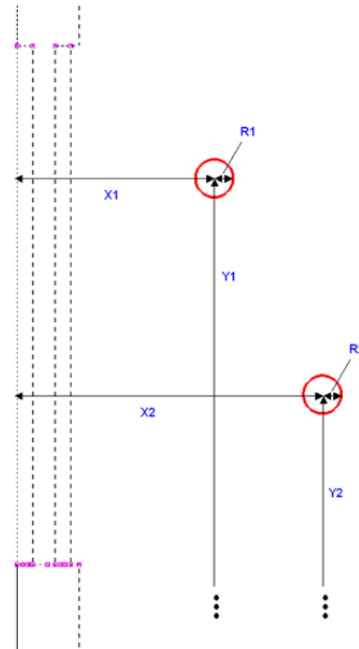

In this example, Simcenter MAGNET Design Optimizer is used with Simcenter MAGNET Electric Field to find where the rings should be placed, and what their dimensions should be, in order to minimize the total electric field stress in the resistors.

RESISTORS ELECTRIC FIELD EQUIPOTENTIAL LINES

The electric field for the surge arrester is obtained using Simcenter MAGNET Electric Field. This figure displays the equipotential lines in the resistors and surrounding air.

IDENTIFYING THE PARAMETERS

This figure shows the parameters that control the placing and the size of the grading rings. In Simcenter MAGNET Design Optimizer, the user specifies a minimum and a maximum value for those variables that can change, and Simcenter MAGNET Design Optimizer limits the searches within this range to find the optimum design.

The goal is to minimize the electric field magnitude in the resistors. In Simcenter MAGNET Design Optimizer, basic quantities, such as the maximum field value in a component, are easily available.

SETTING THE CONSTRAINTS

The screenshot shows the OptiNet software interface with the 'Constraints' tab selected. The table below represents the data shown in the interface:

	Constraint	Argument(s)	Type	Value	W
1	Expression - Model	$\text{Sqr}(X2 - X1)^2 + (Y2 - Y1)^2 < (R1+R2)$ Or $(X1 - R1) < 0.12$ Or $(X2 - R2) < 0.12$	Must be =	False	10
2			Must be =	False	10
3			Must be =	False	10
4			Must be =	False	10
5			Must be =	False	10
6			Must be =	False	10
7			Must be =	False	10
8			Must be =	False	10
9			Must be =	False	10
10			Must be =	False	10
11			Must be =	False	10
12			Must be =	False	10
13			Must be =	False	10
14			Must be =	False	10
15			Must be =	False	10
16			Must be =	False	10
17			Must be =	False	10
18			Must be =	False	10
19			Must be =	False	10
20			Must be =	False	10

The constraints in this optimization process are pure physical ones: the two ring must not overlap and the rings cannot be less than 5mm from the surge arrester.

GRAPH OF VARIABLES

For each iteration of the optimization process, Simcenter MAGNET Design Optimizer updates and displays the changes (in the form of graphs) for the goal, variables, objectives, and constraints -- these graphs are displayed on the Progress page. In this example, each of the six variables' graphs (in groups not exceeding five variables per window) is updated as Simcenter MAGNET Design Optimizer finds a new design.

Simcenter MAGNET Design Optimizer produces a report for each optimization run. In this report, the designs that satisfy the constraints are shown in the order that they are improved. The user can view each design individually. The report also shows the time that it took to arrive at the improved design. The values of all the variables and the optimization function are displayed in this report for each iteration. The values of each parameter can be examined to determine the sensitivity of the design to that particular parameter.

MAXIMUM E FIELD IN THE INITIAL DESIGN

This figure shows the electric field in the three resistors for the initial design that the user supplied to Simcenter MAGNET Design Optimizer, as well as the maximum field magnitude.

MAXIMUM E FIELD IN THE FINAL DESIGN

In the optimum design that Simcenter MAGNET Design Optimizer generated, the maximum electric field in the three resistors is lowered from 146558V/m to 127686 V/m, decreasing by almost 13% the maximum electric field.
